(54) Title: PROPYLENE OLEFIN COPOLYMERS

(57) Abstract

This invention relates to propylene-olefin (PO) copolymers having unique properties described herein as a relationship of mole % olefin to: 1) isotactic index, 2) % meso propylene triad, and 3) glass transition temperature. Specifically, the isotactic index of this invention's copolymers is equal to $-0.0224O+A$ wherein O is the mole % olefin present, A is a number from 66 to 89, and the isotactic index is greater than 0. The propylene tacticity of this invention's polymers is also described by % meso triad equal to $-0.4492O+B$ wherein O is the mole % olefin present, B is a number from 93 to 100, and the % meso triad is less than 95 %. Additionally, the copolymers of this invention have a glass transition temperature equal to $-1.1082O-C$ wherein O is the mole % olefin present and C is a number from 1 to 14.

PROPYLENE OLEFIN COPOLYMERS

10

FIELD OF THE INVENTION

5 This invention relates to propylene/olefin copolymers (PO) having unique
15 properties described herein as a relationship of mole % olefin to: 1) isotactic index,
 2) % meso propylene triad, and 3) glass transition temperature. The olefins include
 C₂-C₂₀ alpha-olefins, the most preferred olefin being ethylene (C₂). Specifically,
20 the isotactic index of this invention's copolymers is equal to -0.0224O + A wherein
 O is the mole % olefin present, A is a number from 66 to 89 and the isotactic index
 is greater than 0. The propylene tacticity of this invention's polymers is also
 described by % meso triad equal to -0.4492EO + B wherein O is the mole % olefin
25 present, B is a number from 93 to 100, and the % meso triad is less than 95%,
 preferably less than 93%, even more preferably less than 90%. Additionally, the
 copolymers of this invention have a glass transition temperature equal to -1.1082O -
 C wherein O is the mole % olefin present and C is a number from 1 to 14. The PO
30 copolymers of this invention are distinguished over prior art PO copolymers by their
 unique crystalline characteristics coupled with elastomeric properties which make
 them useful in a variety of applications such as: thermoplastic elastomers (TPEs),
 impact modifiers and compatibilizers in thermoplastic olefins (TPOs), in elastic
 fibers and films, in dynamically vulcanized alloys (DVAs), as curable elastomers, in
 adhesives, in polyvinyl chloride (PVC) replacements, and in viscosity modifiers.
35 Due to their unique propylene crystallinity, these PO copolymers yield highly
 compatible blends with crystalline polypropylene (PP). These blends have superior
 properties relative to those of blends containing crystalline PP and conventional
 amorphous ethylene-propylene (EP) copolymers. Furthermore, PO copolymers of
40 this invention and their blends with polypropylene (PP) upon orientation give
 significantly enhanced elastic recovery and tensile strength.

45 According to another embodiment of the present invention, the PO
 copolymers of this invention may contain small quantities of a non-conjugated diene
 to aid in the vulcanization and other chemical modification. For purposes of this

5

2

invention, the term "copolymer" is intended to include both polymers formed from ethylene and one or more alpha-olefins and polymers formed from ethylene, one or more alpha-olefins, and one or more non-conjugated dienes. The preferred non-conjugated diene is selected from the group consisting of those monomers useful for vulcanization of ethylene-propylene rubbers, such as, but not limited to, 5-ethylidene-2-norbornene, 1,4-hexadiene, 1,6 octadiene, 5-methyl-1,4 hexadiene, 3,7-dimethyl-1,6-octadiene, vinylnorbornene, dicyclopentadiene or combinations thereof. The amount of diene is preferably less than 10 wt % and most preferably less than 5 wt %.

The polymers of this invention may be prepared by polymerizing a C₂, C₄-C₂₀ alpha olefin preferably ethylene and propylene in the presence of a chiral metallocene catalyst with an activator and optional scavenger.

25

BACKGROUND OF THE INVENTION

15

Metallocenes have been used to make ethylene propylene (EP) copolymers. For example, European Patent Application 128 046 discloses making an EP copolymer with at least two non-chiral metallocenes. However, achiral metallocenes are inherently incapable of making copolymers having an isotactic index greater than 0 and having the other unique crystalline characteristics coupled with elastomeric properties of EP copolymers of this invention.

EP 0 374 695 discloses the preparation of EP copolymers having an isotactic index greater than 0 using a chiral metallocene catalyst with an alumoxane co-catalyst. However, the copolymers of the present invention have an isotactic index equal to -0.0224Et + A wherein Et is the mole % ethylene present, A is a number from 66 to 89, and the isotactic index is greater than 0. This relationship of mole % ethylene to isotactic index is absent in EP 0 374 695 as seen by figure 1. In general, isotactic index of EP copolymers of this invention is significantly lower than that of EP copolymers of EP 0 374 695. The low isotactic index of EP copolymers of this invention is the key to their excellent elastomeric properties.

50

55

5

3

10

U.S. Patent No. 5,504,172 discloses the preparation of EP copolymers having a high % meso triad tacticity of propylene units. However, % meso triad tacticity of propylene units of the copolymers of the present invention is significantly low and equal to $-0.4492E_1 + B$ wherein E_1 is the mole % ethylene present, B is a number from 93 to 100, and the % meso triad is less than 95%. This relationship of mole % ethylene to triad tacticity is seen in the polymers of U.S. Patent No. 5,504,172 as shown by figure 2. The low % meso triad tacticity of propylene units of the copolymers of the present invention is responsible for their excellent elastomeric properties.

35

DETAILED DESCRIPTION OF THE INVENTION

40

The catalyst system described below useful for making the PO copolymers of this invention is a metallocene with a non-coordinating anion (NCA) activator, and optionally a scavenging compound. Polymerization is conducted in a solution, slurry or gas phase, preferably in solution phase. The polymerization can be performed in a single- or multiple-reactor process. A slurry or solution polymerization process can utilize sub- or superatmospheric pressures and temperatures in the range of from -25 °C to 110 °C. In a slurry polymerization, a suspension of solid, particulate polymer is formed in a liquid polymerization medium to which ethylene, alpha-olefin comonomer, hydrogen and catalyst are added. In solution polymerization, the liquid medium serves as a solvent for the

55

polymer. The liquid employed as the polymerization medium can be an alkane or a cycloalkane, such as butane, pentane, hexane, or cyclohexane, or an aromatic hydrocarbon, such as toluene, ethylbenzene or xylene. For slurry polymerization, liquid monomer can also be used. The medium employed should be liquid under the conditions of the polymerization and relatively inert. Preferably, hexane or toluene is employed for solution polymerization. Gas phase polymerization processes are described in U.S. Patent Nos. 4,543,399, 4,588,790, 5,028,670, all of which are herein incorporated by reference for purposes for U.S. Patent Practice. The catalyst may be supported on any suitable particulate material or porous carrier such as polymeric supports or inorganic oxide for example silica, alumina or both. Methods of supporting metallocene catalysts are described in U.S. Patent Nos. 4,808,561, 4,897,455, 4,937,301, 4,937,217, 4,912,075, 5,008,228, 5,086,025, 5,147,949, and 5,238,892, all of which are incorporated by reference for purposes of U.S. Patent Practice.

Propylene and ethylene are the preferred monomers to make the PO copolymers of the invention but ethylene may be replaced with another alpha olefin from C₂ to C₂₀.

Metallocene

The term "metallocene" and "metallocene catalyst precursor" are terms known in the art to mean compounds possessing a Group IV, V, or VI transition metal M, with a cyclopentadienyl (Cp) ligand or ligands which may be substituted, at least one non-cyclopentadienyl-derived ligand X, and zero or one heteroatom-containing ligand Y, the ligands being coordinated to M and corresponding in number to the valence thereof. The metallocene catalyst precursors are generally require activation with a suitable co-catalyst (referred to as activator) in order to yield an active metallocene catalyst which refers generally to an organometallic complex with a vacant coordination site that can coordinate, insert, and polymerize olefins.

Preferable metallocenes are cyclopentadienyl (Cp) complexes which have two Cp ring systems for ligands. The Cp ligands preferably form a bent sandwich

complex with the metal and are preferably locked into a rigid configuration through a bridging group. These cyclopentadienyl complexes have the general formula:

Wherein Cp^1 of ligand $(Cp^1R^1_m)$ and Cp^2 of ligand $(Cp^2R^2_p)$ are preferably the same, R^1 and R^2 each is, independently, a halogen or a hydrocarbyl, halocarbyl, hydrocarbyl-substituted organometalloid or halocarbyl-substituted organometalloid group containing up to 20 carbon atoms, m is preferably 1 to 5, p is preferably 1 to 5, and preferably two R^1 and/or R^2 substituents on adjacent carbon atoms of the cyclopentadienyl ring associated therewith can be joined together to form a ring containing from 4 to 20 carbon atoms, R^3 is a bridging group, n is the number of atoms in the direct chain between the two ligands and is preferably 1 to 8, most preferably 1 to 3, M is a transition metal having a valence of from 3 to 6, preferably from group 4, 5, or 6 of the periodic table of the elements and is preferably in its highest oxidation state, each X is a non-cyclopentadienyl ligand and is, independently, a hydrocarbyl, oxyhydrocarbyl, halocarbyl, hydrocarbyl-substituted organometalloid, oxyhydrocarbyl-substituted organometalloid or halocarbyl-substituted organometalloid group containing up to 20 carbon atoms, q is equal to the valence of M minus 2.

Numerous examples of the biscyclopentadienyl metallocenes described above for the invention are disclosed in U.S. Patents 5,324,800; 5,198,401; 5,278,119; 5,387,568; 5,120,867; 5,017,714; 4,871,705; 4,542,199; 4,752,597; 5,132,262; 5,391,629; 5,243,001; 5,278,264; 5,296,434; and 5,304,614, all of which are incorporated by reference for purposes of U.S. Patent Practice.

Illustrative, but not limiting examples of preferred biscyclopentadienyl metallocenes of the type described in group 1 above for the invention are the racemic isomers of:

- 5 $\mu\text{-}(\text{CH}_2)_2\text{Si}(\text{tetrahydroindenyl})_2\text{M}(\text{Cl})_2$;
 $\mu\text{-}(\text{CH}_2)_2\text{Si}(\text{tetrahydroindenyl})_2\text{M}(\text{CH}_3)_2$;
 $\mu\text{-}(\text{CH}_2)_2\text{Si}(\text{indenyl})_2\text{M}(\text{CH}_2\text{CH}_3)_2$;
10 $\mu\text{-}(\text{C}_4\text{H}_9)_2\text{C}(\text{indenyl})_2\text{M}(\text{CH}_3)_2$;
 5 Wherein m is chosen from a group consisting of Zr, Hf, or Ti.

15 Non-coordinating anions

As already mentioned the metallocene or precursor are activated with a non-coordinating anion. The term "non-coordinating anion" means an anion which either does not coordinate to said transition metal cation or which is only weakly coordinated to said cation thereby remaining sufficiently labile to be displaced by a neutral Lewis base. "Compatible" non-coordinating anions are those which are not degraded to neutrality when the initially formed complex decomposes. Further, the anion will not transfer an anionic substituent or fragment to the cation so as to cause it to form a neutral four coordinate metallocene compound and a neutral by-product from the anion. Non-coordinating anions useful in accordance with this invention are those which are compatible, stabilize the metallocene cation in the sense of balancing its ionic charge, yet retain sufficient lability to permit displacement by an ethylenically or acetylenically unsaturated monomer during polymerization. Additionally, the anions useful in this invention are preferably large or bulky in the sense of sufficient molecular size to largely inhibit or prevent neutralization of the metallocene cation by Lewis bases other than the polymerizable monomers that may be present in the polymerization process. Typically the anion will have a molecular size of greater than or equal to 4 angstroms.

Descriptions of ionic catalysts for coordination polymerization comprised of metallocene cations activated by non-coordinating anions appear in the early work in EP-A-0 277 003, EP-A-0 277 004, U.S. Patents 5,198,401 and 5,278,119, and WO 92/00333. These teach a preferred method of preparation wherein metallocenes (bisCp and monoCp) are protonated by an anionic precursors such that an alkyl/hydride group is abstracted from a transition metal to make it both cationic

5 and charge-balanced by the non-coordinating anion. The use of ionizing ionic
compounds not containing an active proton but capable of producing both the active
10 metallocene cation and a non-coordinating anion is also known. See, EP-A-0 426
637, EP-A-0 573 403 and U.S. Patent 5,387,568. Reactive cations other than
15 Brønsted acids capable of ionizing the metallocene compounds include ferrocenium,
triphenylcarbonium, and triethylsilylum cations. Any metal or metalloid capable of
forming a coordination complex which is resistant to degradation by water (or other
20 Brønsted or Lewis acids) may be used or contained in the anion of the second
activator compound. Suitable metals include, but are not limited to, aluminum,
gold, platinum and the like. Suitable metalloids include, but are not limited to,
boron, phosphorus, silicon and the like. The description of non-coordinating anions
25 and precursors thereto of these documents are incorporated by reference for
purposes of U.S. Patent Practice.

An additional method of making the ionic catalysts uses ionizing anionic
15 pre-cursors which are initially neutral Lewis acids but form the cation and anion
upon ionizing reaction with the metallocene compounds, for example
30 tris(pentafluorophenyl) boron acts to abstract an alkyl, hydride or silyl ligand to
yield a metallocene cation and stabilizing non-coordinating anion, see EP-A-0 427
697 and EP-A-0 520 732. Ionic catalysts for addition polymerization can also be
35 prepared by oxidation of the metal centers of transition metal compounds by anionic
precursors containing metallic oxidizing groups along with the anion groups, see
EP-A-0 495 375. The description of non-coordinating anions and precursors thereto
of these documents are similarly incorporated by reference for purposes of U.S.
40 Patent Practice.

45 Illustrative, but not limiting, examples of suitable activators capable of ionic
cationization of the metallocene compounds of the invention, and consequent
stabilization with a resulting non-coordinating anion include:

- 50 trialkyl-substituted ammonium salts such as;
- 55 triethylammonium tetraphenylborate,

- | | |
|----|--|
| 5 | tripropylammonium tetraphenylborate,
tri(n-butyl)ammonium tetraphenylborate, |
| 10 | trimethylammonium tetrakis(p-tolyl)borate,
trimethylammonium tetrakis(o-tolyl)borate, |
| 15 | tributylammonium tetrakis(pentafluorophenyl)borate,
tripropylammonium tetrakis(o,p-dimethylphenyl)borate,
tributylammonium tetrakis(m,m-dimethylphenyl)borate,
tributylammonium tetrakis(p-trifluoromethylphenyl)borate,
tributylammonium tetrakis(pentafluorophenyl)borate, |
| 20 | tri(n-butyl)ammonium tetrakis(o-tolyl)borate and the like; |
| 25 | N,N-dialkyl anilinium salts such as;
N,N-dimethylanilinium tetrakis(pentafluorophenyl)borate,
N,N-dimethylaniliniumtetrakis(heptafluoronaphthyl)borate, |
| 30 | N,N-dimethylanilinium tetrakis(perfluoro-4-biphenyl)borate,
N,N-dimethylanilinium tetraphenylborate,
N,N-diethylanilinium tetraphenylborate,
N,N-2,4,6-pentamethylanilinium tetraphenylborate and the like; |
| 35 | dialkyl ammonium salts such as;
di-(isopropyl)ammonium tetrakis(pentafluorophenyl)borate,
dicyclohexylammonium tetraphenylborate and the like; |
| 40 | and triaryl phosphonium salts such as;
triphenylphosphonium tetraphenylborate,
tri(methylphenyl)phosphonium tetraphenylborate,
tri(dimethylphenyl)phosphonium tetraphenylborate and the like. |

Further examples of suitable anionic precursors include those comprising a stable carbonium ion and a compatible non-coordinating anion. These include:

55

5 tropyllium tetrakis(pentafluorophenyl)borate,
triphenylmethylium tetrakis(pentafluorophenyl)borate,
benzene (diazonium) tetrakis(pentafluorophenyl)borate,
10 tropillium phenyltris(pentafluorophenyl)borate,
5 triphenylmethylium phenyl-(tris(pentafluorophenyl))borate,
benzene (diazonium) phenyl-tris(pentafluorophenyl)borate,
15 tropillium tetrakis(2,3,5,6-tetrafluorophenyl)borate,
triphenylmethylium tetrakis(2,3,5,6-tetrafluorophenyl)borate,
benzene (diazonium) tetrakis(3,4,5-trifluorophenyl)borate,
20 tropillium tetrakis(3,4,5-trifluorophenyl)borate,
benzene (diazonium) tetrakis(3,4,5-trifluorophenyl)borate,
tropillium tetrakis(3,4,5-trifluorophenyl)aluminate,
triphenylmethylium tetrakis(3,4,5-trifluorophenyl)aluminate,
25 benzene (diazonium) tetrakis(3,4,5-trifluorophenyl)aluminate,
15 tropillium tetrakis(1,2,2-trifluoroethyl)borate,
triphenylmethylium tetrakis(1,2,2-trifluoroethyl)borate,
benzene (diazonium) tetrakis(1,2,2-trifluoroethyl)borate,
30 tropillium tetrakis(2,3,4,5-tetrafluorophenyl)borate,
triphenylmethylium tetrakis(2,3,4,5-tetrafluorophenyl)borate,
benzene (diazonium) tetrakis(2,3,4,5-tetrafluorophenyl)borate, and the like.
35 A particularly preferred catalyst system is $\mu\text{-}(\text{CH}_3)_2\text{Si(indenyl)}_2\text{Hf}(\text{CH}_3)_2$ with a cocatalyst of N,N-dimethylanilinium tetrakis(pentafluorophenyl)borate.

40 Ethylene Propylene Copolymers

45 25 EP copolymers of this invention have unique properties as evidenced by the relationship of their isotactic index and propylene triad tacticity to their ethylene content. Isotactic index and triad tacticity were determined for this invention's EP copolymers in the manner described below.

50 30 35 Copolymers of this invention can be blended with processing oil and other common additives such as nucleating agents, antioxidants, fillers, etc. and fabricated into objects used in a variety of applications mentioned above.

5

10

Also, blends comprising the copolymers of this invention and other alpha-olefin polymers and copolymers, e.g., polypropylene, are fabricated into objects used in a variety of applications mentioned above. Generally, these blends contain processing oil and other common additives such as nucleating agents, antioxidants, fillers, etc.

15

Polydispersity Index

Copolymers of the invention preferably have a polydispersity index (M_w/M_n) of from 1.5 to 10, more preferably from 1.8 to 8, even more preferably from 2.0 to 5.

20

Isotactic Index

Polypropylene isotactic index is determined by infra-red (IR) spectroscopy. The IR spectra of polypropylene yields two observable peaks at 997 cm^{-1} and 973 cm^{-1} . The quotient of absorbance at 997 cm^{-1} divided by the absorbance at 973 cm^{-1} is a recognized measure of isotacticity. Polypropylene isotactic index is defined as this quotient multiplied by 100.

30

The EP copolymers made by this invention have unique crystalline characteristic as measured by isotactic index. Figure 1 is a graph depicting the relationship of isotactic index of a given copolymer to its mole % ethylene content. The data from this invention's copolymers and EPA 037659 are plotted on the graph. As shown by Figure 1, the copolymers of this invention have a lower isotactic index for any given ethylene content when compared to EPA 037659. The lower isotactic index corresponds to relatively lower crystallinity that translates into better elastomeric properties such as high tensile strength and elongation at break coupled with very good elastic recovery. Good elastomeric properties are important for some of the potential applications mentioned above.

45

Triad Tacticity

50

The term "tacticity" refers to the stereogenicity in a polymer. For example, the chirality of adjacent monomers can be of either like or opposite configuration.

55

5

The term "diad" is used to designate two contiguous monomers; three adjacent monomers are called a triad. If the chirality of adjacent monomers is of the same relative configuration, the diad is called isotactic; if opposite in configuration, it is termed syndiotactic. Another way to describe the configurational relationship is to term contiguous pairs of monomers having the same chirality as meso (m) and those of opposite configuration racemic (r).

10

5

When three adjacent monomers possess are of the same configuration, the stereoregularity of the triad is 'mm'. If two adjacent monomers in a three-monomer sequence have the same chirality and that is different from the relative configuration of the third unit, this triad has 'mr' tacticity. An 'rr' triad has the middle monomer unit having an opposite configuration from either neighbor. The fraction of each type of triad in the polymer can be determined and when multiplied by 100 indicates the percentage of that type found in the polymer.

15

The triad tacticity can be determined from a ^{13}C -NMR spectrum of the propylene copolymer. The ^{13}C -NMR spectrum is measured in the following manner. To measure the ^{13}C -NMR spectrum, 250-350 mg of polymer is completely dissolved in deuterated tetrachloroethane in a NMR sample tube (diameter: 10 mm)

20

10

at 120° C. The measurement is conducted with full proton decoupling using a 90° pulse angle and at least a 15 second delay between pulses

25

With respect to measuring the chemical shifts of the resonances, the methyl group of the third unit in a sequence of 5 contiguous propylene units consisting of head-to-tail bonds and having the same relative chirality is set to 21.83 ppm. The chemical shift of other carbon resonances are determined by using the above-mentioned value as a reference. The spectrum relating to the methyl carbon region

30

(17.0-23 ppm) can be classified into the first region (21.1-21.9 ppm), the second region (20.4-21.0 ppm), the third region (19.5-20.4 ppm) and the fourth region (17.0-17.5 ppm). Each peak in the spectrum was assigned based on the work described in Polymer, Vol. 30 (1989) p. 1350, or Macromolecules, Vol. 17 (1984) p. 1950.

50

55

5

In the first region, the signal of the center methyl group in a PPP (mm) triad is located.

10

In the second region, the signal of the center methyl group in a PPP (mr) triad and the methyl group of a propylene unit whose adjacent units are a propylene unit and an ethylene unit resonates (PPE-methyl group).

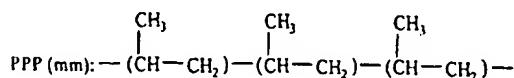

15

In the third region, the signal of the center methyl group in a PPP (rr) triad and the methyl group of a propylene unit whose adjacent units are ethylene units resonate (EPE-methyl group).

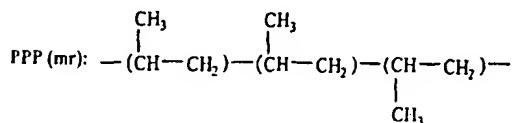

20

PPP (mm), PPP (mr) and PPP (rr) have the following three-propylene units-chain structure with head-to-tail bonds, respectively.

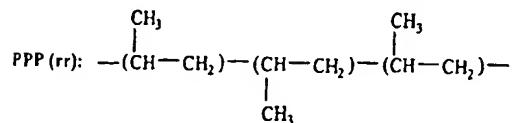

25

30

35

40

The triad tacticity (mm fraction) of the propylene copolymer can be determined from a ^{13}C -NMR spectrum of the propylene copolymer and the following formula:

45

$$\text{mm Fraction} = \frac{\text{PPP (mm)}}{\text{PPP (mm)} + \text{PPP(mr)} + \text{PPP(rr)}}$$

50

20

55

5

The peak areas used in the above calculation are not measured directly from the triad regions in the CNMR spectrum. The intensities of the *mr* and *rr* triad regions need to have subtracted from them the areas due to EPP and EPE sequencing, respectively. The EPP area can be determined from the signal at 30.8 ppm after subtracting from it one half the area of the sum of the signals between 26 and 27.2 ppm and the signal at 30.1 ppm. The area due to EPE can be determined from the signal at 33.2 ppm.

10

5

15

In addition to the above adjustments to the *mr* and *rr* regions for the presence of EPP and EPE other adjustments need to be made to these regions prior to using the above formula. These adjustments are needed to account for signals present due to non-head-to-tail propylene additions. The area of the *mr* region may be adjusted by subtracting one half of the area between 34 and 36 ppm and the area of the *rr* region may be adjusted by subtracting the intensity found between 33.7 and 40.0 ppm. Therefore, by making the above adjustments to the *mr* and *rr* regions the signal intensities of the *mm*, *mr* and *rr* triads can be determined and the above formula applied.

20

30

20

35

40

45

The EP copolymers made by this invention have unique propylene tacticity as measured by % meso triad. Figure 2 is a graph depicting the relationship of % meso triad of a given copolymer to its mole % ethylene content. The data from this invention's copolymers and U.S. Pat. No. 5,504,172 are plotted on the graph. As shown by figure 2, the copolymers of this invention have a lower % meso triad for any given ethylene content when compared to U.S. Pat. No. 5,504,172. The lower content of % meso triads corresponds to relatively lower crystallinity that translates into better elastomeric properties such as high tensile strength and elongation at break coupled with very good elastic recovery. Good elastomeric properties are important for some of the potential applications mentioned on page 1.

Copolymer Properties

30

50

Various techniques were used to characterize the copolymers of this invention some of which are described in "Structure Characterization" The Science

55

5

and Technology of Elastomers, F. Einrich, editor, Academic Press 1978, Chapter 3 by G. Ver Strate which is incorporated by reference for purposes of U.S. Patent Practice.

10

15

Glass transition temperature (T_g) of polymer is usually measured by differential scanning calorimetry (DSC). The T_g of EP copolymers reported in this application is determined by either modulated DSC (MDSC) technique or conventional DSC technique.

20

The copolymer of the invention preferably has a reactivity ratio product (r_1r_2) equal to or less than 2.5.

25

25

Conventional DSC Technique: DSC has a standard protocol of loading a calorimeter at 20 °C with a specimen free of molding strains, cooling the sample to -75 °C, scanning to 180 °C at 10 °C/min., cooling to -75 °C, and re-running the scan. The T_g and melting point (T_m) are evaluated.

30

Modulated DSC Technique: Thermal analyzer instruments' model 2910 is used. 5-10 mg of polymer sample is loaded in the instrument at ambient temperature. The general analysis procedure calls for subjecting the sample to the following thermal segments in the order given below:

35

1. From room temperature, ramp 10 °C/minute to -60 °C.
2. Isothermal for 1.0 minute.
3. Simultaneously modulate +/- 1.0 °C every 60 seconds and ramp 5 °C/minute to 150 °C.
4. Isothermal for 1.0 minute.
5. Ramp 5 °C/minute to -10 °C.
6. Isothermal for 1.0 minute.
7. Ramp 10 °C/minute to 150 °C.
8. Ramp 10 °C/minute to 25 °C.

50

55

5

Data is acquired and analyzed using Thermal Analyzer Instruments' Model 2200 computer and the T_g , Melting Point (T_m) and Crystallization Point (T_c) are evaluated.

10

High-Temperature GPC (HT-GPC)

5

SCOPE

15

Gel permeation chromatography (GPC) is a liquid chromatographic technique which separates macromolecules according to their hydrodynamic size. It is employed here to obtain the molecular weight distribution of polyolefin samples (e.g., PE and PP). A dilute solution of the polyolefin in a good solvent (1,2,4-trichlorobenzene, TCB) is carried through a series of separation columns filled with porous packing material (rigid particles of cross-linked styrene/divinyl benzene gel) using a mobile phase (also TCB) at constant flow rate. Separation occurs by repeated exchange of the polymer molecules between the bulk solvent and the pores of the packing material. The distribution of pore sizes thus determines the size range over which separation occurs, as well as the extent of separation, with large molecules eluting before smaller ones. After separation, a Differential Refractive Index (DRI) detector is used to measure polymer concentration as a function of elution time (or elution volume). A pre-established calibration curve, based on polystyrene standards, allows this raw data to be converted into concentration vs molecular weight data. The number, weight, and z-average molecular weights (M_n , M_w , and M_z , respectively) are then calculated from these results.

20

25

30

35

40

45

50

CALIBRATION

A set of columns are calibrated by running a series of narrow molecular weight polystyrene standards (Tosoh Corp., Japan) and recording their peak retention (elution) times. A total of 16 PS standards are used, covering a molecular weight range of M_{PS} = 500-5,000,000. PE and PP molecular weight vs retention time data are calculated from these results by assigning PE- or PP-equivalent

55

5

molecular weights for each PS standard. Final calibration curves for PE and PP then consist of 3rd-order polynomial fits of these data sets.

10

For PP, the "universal calibration" approach is adopted, in which $M_{PS}[\eta]_{PS}$ = $M_{PP}[\eta]_{PP}$ is assumed to hold. The following Mark-Houwink coefficients are employed in the relation $[\eta] = kM^\alpha$:

15

20

	$k(dL/g)$	α
PS	1.75×10^{-4}	0.67
PP	8.33×10^{-4}	0.80

25

RUN CONDITIONS

10 INSTRUMENT: Waters 150-C GPC
 COLUMNS: 3 Shodex AT-806MS (mixed bed)
 MOBILE PHASE: filtered TCB, 300 ppm antioxidant (Santonox)
 15 TEMPERATURE: 145 °C (column and injector compartments)
 RUN TIME: 50 minutes
 20 INJECTION VOLUME: 300 µL
 FLOW RATE: 1.0 mL/min
 25 DRI SENSITIVITY: 256
 DRI SCALE FACTOR: 16

35

SAMPLE PREPARATION

40 4-6 mg of polymer is weighted into a 4 mL WISP vial, sufficient TCB is added to yield a concentration of 1.5 mg/mL, and the vial is capped with a PTFE septum and labeled with the work request number. Preferably, TCB from a single source is used for both sample preparation and the mobile phase to minimize 45 instability in the DRI signal as the lowest molecular weight components elute (i.e., 50 "solvent mis-match" peaks). The sample is placed in the shaker oven at 160-170 °C

55

5

10

5

15

20

25

30

35

40

50

for 3-4 hours while continuously agitating at a rate of 120-160 rpm. After discarding samples that contain undissolved gel or solid particles, the vials are transferred to a pre-heated sample carousel, and the carousel quickly placed into the heated injector compartment of the GPC. The set of samples are run according to the directions for normal operation in the waters 150-C GPC manual.

DATA ACQUISITION AND ANALYSIS

Data is acquired and analyzed using Waters "Expert Ease" software. Samples are identified by the work request and customer notebook numbers. For a given chromatogram, a linear baseline is established based on the pre-peak trend, and the limits for peak integration are set by estimating the points of initial and final deviation of the signal from that baseline (and excluding "solvent mis-match" or "injection" peaks). The established calibration curve, appropriate for PE or PP, is used to convert the DRI signal vs retention time data to molecular weight distribution data. M_n , M_w , M_z , and recovered mass (relative to the control sample) are calculated by the software. A report is generated that includes these values, a plot of the raw retention time data, and a plot of the molecular weight distribution. A "time slice" report is also available.

The EP copolymers made by this invention have unique properties as measured by T_g . Figure 3 is a graph depicting the relationship of T_g of a given copolymer to its mole % ethylene content. The data from this invention's copolymers are plotted on the graph.

EXAMPLES I-3

The polymers of Examples 1-3 were made with the following general procedure. Polymerizations were carried in a one liter stirred reactor with continuous flow of feeds to the system and continuous withdrawal of products. Solvent, including hexane, and monomers including ethylene and propylene were purified over beds of alumina and mole sieves. Toluene for preparing catalyst

5

10

15

20

25

30

35

40

45

solutions was also purified by the same technique. All feeds were pumped into the reactors by metering pumps except for the ethylene which flowed as a gas under its own pressure through a mass flow meter/controller. Reactor temperature was controlled by circulating water through a reactor cooling jacket. The reactor was maintained at a pressure in excess of the vapor pressure of the reactant mixture to keep the reactants in the liquid phase. The reactor was operated liquid full.

Ethylene and propylene feeds were combined into one stream and then mixed with a pre-chilled hexane stream that had been cooled to at least 0 °C. A hexane solution of triisobutyl aluminum scavenger was added to the combined solvent and monomer stream just before it entered the reactor to further reduce the concentration of any catalyst poisons. A catalyst solution was prepared by dissolving $\mu\text{-Me}_2\text{Si(indenyl)}_2\text{HfMe}_2$ catalyst and (N,N dimethylaniliniumtetrakis(pentafluorophenyl) borate ([DMAH]B(pfp)₄) activator in dry toluene. This mixture of the catalyst components in toluene was pumped separately to the reactor and entered through a separate port. The product from reactor exited through a pressure control valve that reduced the pressure to atmospheric. This caused the unconverted monomers in the solution to flash into a vapor phase which was vented from the top of a vapor liquid separator. The liquid phase, comprising mainly polymer and solvent, flowed out the bottom of the separator and was collected for polymer recovery. Polymer was recovered from solution by either steam stripping following by drying, or by solvent evaporation under heat and vacuum. Below, Table 1 shows polymerization conditions for Examples 1-3.

TABLE I

Example #	Polymn Temp. (C)	Feed Rates (gm/hr)				Polymn. Time (min)	Polymer Yield (gm)
		C ₂	C ₃	Catalyst	Scavenger		
1	70	45	335	0.00934	0.000706	30	1061
2	60	18	428	0.00934	0.000706	30	1067
3	61	45.6	502	0.00969	0.00047	20	724

25

50

55

5

EXAMPLES 4-6

10

The polymers of Examples 4-6 were made with the following general procedure. A 5 gallon autoclave stirred tank reactor, equipped with an external jacket for temperature control, was charged with 29 pounds of dry toluene (diluent).

15

Hexane or other inert hydrocarbon solvent may be used in place of toluene. Next, 40 grams of 25% solution of triisobutyl aluminum scavenger was charged to the reactor. The contents of the reactor were stirred and maintained at a certain initial temperature shown in table 2. Generally, ethylene (C_2) and propylene (C_3) feed

20

lines were tied together to obtain a premixed monomer feed that is fed into the reactor via a single dip tube. Alternatively, ethylene and propylene may be fed directly to the reactor through individual entry tubes. The flow rates of ethylene and

25

propylene were adjusted to give desired C_3 / C_2 monomer ratio. A catalyst solution, containing 121 mg of $\mu\text{-Me}_2\text{Si}(\text{Indenyl})_2\text{HfMe}_2$, and 151 mg of N,N-

30

Dimethylanilinium tetrakis(pentafluorophenyl)boron in 100 ml of dry toluene, was charged in a catalyst bomb. This bomb was a part of a catalyst delivery setup capable of delivering 15 ml of catalyst solution per addition to the reactor. Initially,

35

30 - 45 ml of catalyst solution was added to the reactor to induce polymerization. Additional catalyst solution is added at desired time intervals during the

40

polymerization. Reactor pressure, temperature and C_3 & C_2 flow rates were monitored throughout the polymerization run that typically lasts for 10 - 30 minutes.

After a certain time period, the reactor effluent was transferred, under nitrogen pressure, to a devolitizing unit. A continuous flow of steam was introduced in this

unit for a long period of time to insure evaporation of diluent. Vacuum was usually applied to accelerate devolitization of diluent. Copolymer floated on top of water

when most of the solvent was evaporated. It was isolated, dried and characterized.

Reaction conditions for Examples 4-6 are shown in Table 2 below.

45

50

55

5

Table 2

	Example #	Initial Reaction Temp.	Final Reaction Temp.	$\Delta t =$ Final t - Initial t	Catalyst Addition Sequence	Average C ₃ / C ₂ (12M.b)	Polymerization time	Crude Polymer Yield

	5	9° c	25° c	16° c	30 ml initially 15 ml after 3 min. 15 ml after 6 min. Of polymerization	6.8	10 min.	~2 Lbs
15	6	9° c	28° c	19° c	30 ml initially 15 ml after 7 min. 15 ml after 11 min. Of polymerization	13.2	20 min.	~2 Lbs

EXAMPLE #7

20

600 ml of dry toluene (diluent) was introduced in a dry, deoxygenated 1L autoclave reactor equipped with stirrer and an external jacket for temperature control. Temperature of the reactor is lowered to 0° C. From a propylene feed vessel (volume 1.1L), 120 psi (ΔP) of purified propylene gas was fed into the reactor. After equilibration of reactor pressure, 25 psi (ΔP) of purified ethylene gas was introduced into the reactor. This procedure gave a desirable C₃ / C₂ monomer ratio for the synthesis of EP copolymers containing a high amount of C₃. The catalyst solution was prepared in a dry box and transferred into A catalyst feed tube. It contained 24 mg of μ -Me₂Si(Indenyl)₂HfMe₂ and 15 mg of N,N-Dimethylanilinium tetrakis(pentafluorophenyl)boron in 5 ml of dry toluene. Polymerization was induced at 0° C by injecting the catalyst solution into the reactor. Reactor pressure and temperature was monitored throughout the polymerization. A temperature jump of 9° C was observed over a period of 6 minutes after the addition of the catalyst solution. After the initial jump, the reactor temperature leveled off and decreased with increasing polymerization time. Reactor pressure decreased gradually during the polymerization. The reactor was vented completely after 20 minutes of polymerization and the contents of the reactor were poured into a beaker containing large excess of acetone. The precipitated polymer was dried under vacuum at 100° C for 24 hours. The polymer yield was 19.3 gm.

50

55

5

EXAMPLE #8

500 ml of dry toluene (diluent) was introduced in a dry, deoxygenated 1L autoclave reactor equipped with stirrer and an external jacket for temperature control. Temperature of the reactor was lowered to -10° C. A catalyst solution containing 12 mg of $\mu\text{-Me}_2\text{Si(Indenyl)}_2\text{HfMe}_2$ and 10 mg of N,N-Dimethylanilinium tetrakis(pentafluorophenyl)boron in 5 ml of dry toluene was injected in the reactor. The reactor was maintained under a slight positive pressure of dry nitrogen. Polymerization was induced at -10° C by introducing a gaseous mixture of C₂ and C₃ into the reactor. The molar ratio of C₂:C₃ in this mixture was 3.5:1. The flow of monomer mixture continued from the feed vessel to reactor until there is no pressure difference between the two. At this time the reactor inlet valve was shut off and polymerization was continued. Reactor pressure and temperature was monitored throughout the polymerization. A temperature jump was observed of 18° C (-10° C to 8° C) over a period of 5 minutes since the introduction of the monomer mixture in the reactor. After the initial jump, the reactor temperature leveled off and decreased with increasing polymerization time. Reactor pressure decreased gradually during the polymerization. The reactor was vented completely after 20 minutes of polymerization and the contents of the reactor were poured into a beaker containing large excess of acetone. The precipitated polymer was dried under vacuum at 100 °C for 24 hours. The polymer yield was 20 gm.

While the present invention has been described and illustrated by reference to particular embodiments, it will be appreciated by those of ordinary skill in the art that the invention lends itself to variations not necessarily illustrated herein. Reference should be made solely to the appended claims and their equivalents for purposes of determining the true scope of the present invention. For example, fabricated products comprising the claimed copolymer of this invention are also part of this invention. Such fabricated products can also optionally comprise one or more of an alpha olefin polymer or copolymer, a processing oil, and other additives. One such particularly preferred alpha olefin polymer is polypropylene.

CLAIMS.

1. A propylene/olefin copolymer wherein said copolymer has:
 - (a) an isotactic index equal to $-0.0224O + A$ wherein O is the mole % olefin present, A is a number from 66 to 89, and the isotactic index is greater than 0;
 - (b) a % meso triad of equal to $-0.4492O + B$ wherein O is the mole % olefin present, B is a number from 93 to 100, and the % meso triad is less than 95%.
- 10 2. The copolymer of claim 1 wherein said olefin is ethylene.
- 15 3. The copolymer of claim 1 or 2 having a glass transition temperature equal to $-1.1082Et - C$ wherein Et is the mole % ethylene present and C is a number from 1 to 14.
- 20 4. The copolymer of any of the above claims with an ethylene content from 10 to 35 mole %.
- 25 5. The copolymer of any of the above claims with number average M_w from 15,000 to 2,000,000 and an M_w/M_n ratio from 1.5 to 10.
- 30 6. The copolymer of any of the above claims having a T_g of from 25-125° C.
- 35 7. The copolymer of any of the above claims having a reactivity ratio product ($r_1 \times r_2$) equal to or less than 2.5.
- 40 8. An article of manufacture comprising the copolymer of any of the above claims, optionally blended with one or more of other alpha olefin polymers and copolymers, processing oil, an other additives.

50

55

25

5

9. The article of claim 8 wherein said copolymer is blended with polypropylene.

10

10. The article of claim 8 or 9 wherein said copolymer blend is oriented.

5

15

11. A process for making the copolymer of claim 1 comprising polymerizing propylene and a C₃-C₂₀ alpha olefin with a metallocene and an activating cocatalyst.
